JOB MARKET PAPER

Aggregate Implications of Corporate Lending by Non-Financial Firms

Abstract: Beginning in the early 1990s, the share of risky securities held by U.S. nonfinancial firms increased from 28% of total financial assets to more than 40% by the end of 2017. I start by empirically showing that in the Great Recession, firms with a high share of risky financial assets suffered, on average, a larger investment drop. Making use of a business-cycle heterogeneous firms model amplified with a savings portfolio decision, where the risky asset are corporate bonds, I argue the decrease in the real interest rate since the 1980s generates a rise in the risk premium consistent with the data and can fully account for the observed increase in risky asset holdings. This portfolio reallocation causes capital to decrease by up to 30% more following a large shock that generates a decrease in investment similar to the Great Recession. The exposure of firms to corporate bonds ends up creating a financial linkage between firms and propagates the shock from defaulting borrowers to lenders.
